Researching Online Learning Activities: What counts?

Abstract: Researching online offers endless possibilities for educators regardless of how the environment need to be understood and analysed. The emergence of the internet creates accessibility and opportunities for asynchronous and synchronous communication. Despite its advantages, research on online teaching and learning do represent problems in terms of observing the activities as meaningful learning are concerned. The activities of teaching and learning often vary and sometimes misunderstood. Teachers should no longer be viewed as the main source of knowledge. Likewise, students should no longer be seen as individuals who only absorb what is taught. Through discussion, students mutually learn from each other (peer-learning). This study investigates ‘teaching’ behavior evidenced in activities involving a group of university students using the Learning Management System (LMS) as a tool for discussion. This paper aims to address part of the problems that are faced by researchers when exploring the online tasks in the teaching-learning process, namely in trying to find meaningful contributions from learning participations in non-experimental conditions. Taking a sociocultural perspective, an argument is offered for the theorisation of peer to peer learning as a variety of ‘assisted performance’. Using this theoretical lens, a case study is then offered which uses this model to frame an analysis of the nature and occurrences of online exchanges between students and the tutors. Assisted performance categories were used to analyse the message transactions and they are: Scaffolding, Feedback on Performance, Cognitive Structuring, Modelling, Contingency Management, Instructing and Questioning. The problems discussed in this paper focus on the difficulties when facing a unique form of qualitative data for indication of activities particularly the ‘assistances’ and the capacities of assistance in the learning tasks, which is analysed by quantitative means – Content Analysis. Analysis reveals the problems in researching online learning tasks in the aspects of methodology which is in trying to find what is most significant for evidence of meaningful postings. Instead of looking at the number of messages or number of assistances, researchers have found the solutions by taking ‘proportions’ of assisted performance in the learning performance. Teaching behaviour could be occurring in peer learning in students’ interactions that were evidenced in online learning tasks in this study.

Keywords: Assisted performance; Online Learning; Peer Learning; Learning tasks; Learning activities.

Introduction

Educators are often challenged by the ongoing debate on learning design [1] [2] [3] for online learning especially when initiating tasks to get the utmost involvement from students. With the advent of technologies in the form of the Internet, the possibilities of asynchronous and synchronous practices become inevitable; both presenting its own challenges.

Recent studies have documented how online learning; a form of network-based teaching and learning that links learners using Internet-mediated communication tools, can be used
as a face-to-face session alternative for meeting a range of pedagogical goals [4] [5] [6]. [7] and [2] emphasise that ‘activities’ and ‘tasks’ are distinguishable in which “tasks are required of learners by the demands of the curriculum. Meanwhile, activities are engaged in by learners in response to the demands of a task” [2]. Attention has recently turned to look at evidences of both learning activities and tasks taking place in an online learning environment ([8], [3]). However, the key problem identified in this research methodology is in trying to look at the evidence of learning activities in the records of online learning tasks.

The study was intended to investigate the occurrences of ‘teaching’ behaviour in peer learning in online discussion and how are they different to tutors’ behaviours, and how these roles are enacted within tasks. Having defined teaching as assisted performance [9], the strategy for the study was to look at the occurrence and nature of assisted performance in CMC in higher education courses (that used CMC to extend the face-to-face discussion). However, for the purpose of this paper, two main problems are highlighted here with solutions which are proposed to be useful in handling such problems which are: (1) determining evidence; and proceed to the next step (2) what should be counted?

1. Assisted performance in Learning Interaction

Existing research predominantly acknowledges the need for support in order to achieve productive interactions in online learning environments. Littleton concludes in the final chapter of Learning with Computers – Analysing productive interaction: ‘Underpinning many of the contributors’ interest in understanding productive interaction is that through the study of collaborative interactions we can come to understand how better to support learners’ joint endeavours’ [10]. An alternative concept to support is offered by Rogoff [11] in the form of guided participation. The crucial factor of this concept is that it emphasises on participation, which has important implications for ‘how children gain knowledge from social interaction’.

Communication between children and their caregivers involves two focal processes: creating bridges, and structuring the children’s participation. This process shows how learners could be assisted: first, by developing an engaging atmosphere for participation between learner and the other parties; and second, by monitoring and managing the learner’s participation. However, the concept of ‘guided participation’ is different for a study that involved more than one learner participating in the learning activities together. In terms of scope of observation: ‘The concept of guided participation is used in an attempt to keep individual, interpersonal, and cultural processes simultaneously in focus, representing inseparable aspects of whole events in which children and communities develop’ [12]. The question here is whether this notion of assistance can persist in an online environment when all the other non-textual manifestations are absent. Furthermore, it could be argued, students still may be able to learn in online learning contexts, without participating or communicating with other group members. Indeed there is a question of whether contributors to an online forum do in fact represent a community of practice rather than a group who choose to share an affinity space [13].

The term ‘scaffolding’ has been generally attributed to Wood, Bruner, and Ross [14] who describe it as a: ‘process that enables a child or a novice to solve a problem, carry out a task or achieve a goal which would be beyond his unassisted efforts’. The term is used as a metaphor for the situation in which an adult assists a child to carry out a task beyond the
child’s capability. This metaphor is parallel to the concept of the Zone of Proximal Development (ZPD), developed by Vygotsky. The term ‘scaffold’, like the term ‘support’, has been used more widely in the literature as, generally, the concept of scaffolding has been accepted and applied in educational settings (e.g. [15]; [16]; [17]; [18]; [19]; [20]; and [21]). Compared to ‘support’, ‘scaffolding’ is seen as more theoretical and therefore there were efforts by educational practitioners to re-conceptualise the term. However, assistance goes beyond scaffolding and Tharp and Gallimore [9] put forward reasons why the ‘scaffold’ metaphor needs more refinement:

the field has advanced to the point that a more differentiated concept can be developed. For example, scaffolding suggests that the principle variations in adult actions are matters of quantity – how high the scaffold stand, how many levels it supports, how long it is kept in place. But many of the acts of the adult in assisting the child are qualitatively different from one another. [9]

Given the above discussion, this paper highlights the importance of ‘assistance’ rather than ‘support’, ‘guided construction’ and ‘scaffolding’. The reason for using ‘assistance’ rather than ‘support’ is to humanise this particular action. Similarly, ‘guided construction’ is not used as it does not stress the assistance provided by the person or persons around the learner and the word ‘construction’ emphasises the processes only on the learner side. As to the data availability factor (which is obtained through messages only, the full process of the activities that took place could not be captured hence, the concept of ‘guided participation’ was not reflected in this study. The ‘scaffolding’ concept is important for understanding how ‘help’ could be given through interactions. However, the terms/assumptions presented above imply intent on the part of the provider, which it is not always the case. Someone might assist another person’s performance just simply by stating what s/he thinks, or by asking a question the reader had not thought of. Therefore, ‘assisted performance’ and the categories developed from this notion were seen as suitable for the study described here, which intends to identify meaningful peer supported learning interactions, through seeking for evidence of assistance provision. The following categories developed by Gallimore and Tharp [22] adapted in Kirkley et al. [23] were used to analyse the message transactions, or means of assistance, in CMC ‘Discussion Board’. They are: Scaffolding, Feedback on Performance, Cognitive Structuring, Modelling, Contingency Management, Instructing and Questioning.

If teaching is defined as assisted performance [9], the categories of assisted performance suggest that teaching behaviour can also be seen in the students’ contributions. For example, assistance in the form of questioning and modelling may be serendipitously delivered by anyone participating in online discussions. Assisted performances provided by the participants in online discussion are therefore the evidences of occurrences of opportunities for learning through social interactions [24] [25].

If assisted performance is indeed a useful theorisation of peer to peer learning, the questions that arise are what would it look like in an online discussion, and is there any evidence to support this interpretation of online interaction? To understand the nature of assisted performance in online discussions, the following research questions were developed:

1. Do students offer assisted performance within online discussion threads and how are they different to tutors?
2. What types of assistances are provided by students compare to tutors?
2. Methodology

2.2 Participants

This study involved a total of 48 participants consisting of 36 students and 12 tutors. The 36 students represented two groups of 19 and 23 students respectively. Both groups consisted of tutors and students in a Masters programme. The programme ran on a one-year basis for the full-time students and up to five years for the part-time students. It consists of eight taught units and a dissertation. Six of ten part-time students in the first group were also enrolled in the second group. Even though there were two series of year group used, entire units were not included in the study. Seven out of eight units in the first year and six out of eight units in the second year were chosen for this study. Some units were not included in the study because they had used the CMC too little or not at all. In this study, the first group is labelled ‘Year 1’ and the second group is labelled ‘Year 2’. Most of the findings are presented according to year groups, (i.e. Year 1 and Year 2) to get an overview of the pattern of assistance.

2.3 Procedures

Assistance offering and giving, captured in the messages, are evidence of teaching in this context. Content analysis was one method used to investigate the circumstance of assistance through discussion. All circumstances of assistance, such as the total number of assistance and types of assistance by group (units), role and different task types were counted and diagnosed. Content analysis was performed on all the messages in the ‘Forum’ for all courses selected. Quantitative analysis of the data, through regularities or frequencies, showed the nature of assistance in tutor-student/s and student-student interaction.

3. Methodological issues

3.1 Number of messages, number of assistance or the portion of the messages?

It should be noted that analysing information regarding the number of messages is rather conventional. Regardless of how conventional this type of analysis is, the total number of messages per se has little significance. Rather, this study clearly exhibits that, the key variable in fact, is the number of incidences of assistance provision in the messages. Accordingly, the number of assistance on it own is still less meaningful as it is dependable to the number of messages. An alternative term might be: the ‘proportion’ of assistance. The proportion of assistance can be obtained with the following equation of:

\[
\text{Proportion} = \frac{\text{number of assistances}}{\text{number of messages}} \times 100
\]

This equation helps to answer the question, in any given message, what is the probability of an instance of assistance? It is very important to keep in mind that ‘assistance’ throughout the analysis refers to the instances of assistance, rather than occurrences of messages because one sent message could contain more than one instance of assistance.
Table 1: Overall number of messages posted by the participants in each unit

<td>26</td>
<td>37</td>
<td>96</td>
<td>14</td>
<td>-</td>
<td>-</td>
<td>45</td>
<td>306</td>
</tr>
</tbody>
</table>

As an example, this sub-section identifies the pattern of assistance provision (assistance given by the tutor and the students) across the units in each year group. Numbers of messages posted according to units in each year group are as follows:

Table 2: Overall number of assistance given by the participants in each unit

<table>
<thead>
<tr>
<th>Unit in Year 1</th>
<th>1-1</th>
<th>2-1</th>
<th>3-1</th>
<th>4-1</th>
<th>5-1</th>
<th>6-1</th>
<th>7-1</th>
<th>8-1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total assistance</td>
<td>197</td>
<td>54</td>
<td>33</td>
<td>53</td>
<td>29</td>
<td>16</td>
<td>150</td>
<td>-</td>
<td>532</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Unit in Year 2</th>
<th>1-2</th>
<th>2-2</th>
<th>3-2</th>
<th>4-2</th>
<th>5-2</th>
<th>6-2</th>
<th>7-2</th>
<th>8-2</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total assistance</td>
<td>138</td>
<td>52</td>
<td>21</td>
<td>131</td>
<td>19</td>
<td>-</td>
<td>-</td>
<td>32</td>
<td>393</td>
</tr>
</tbody>
</table>

The total number of messages in both groups is unequal and there is no specific pattern for the number of messages posted. This inequality is partly because there were more units in Year 1 that had active discussion groups. Moreover, the number of participants in each year varies. As mentioned earlier, the total number of messages is not what is significant here; rather it is the number of incidences of assistance provision that is the key variable in this study. Therefore, the information on number of assistance provision instances is as follows:

To get the exact proportion of assistance in the messages posted in each unit, the number of assistance is divided by the number of messages and multiplied by a hundred. The outcomes are as follows:

Table 3: Overall proportion of assistance in each unit

<table>
<thead>
<tr>
<th>Unit in Year 1</th>
<th>1-1</th>
<th>2-1</th>
<th>3-1</th>
<th>4-1</th>
<th>5-1</th>
<th>6-1</th>
<th>7-1</th>
<th>8-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instances of assistance</td>
<td>158.9</td>
<td>61.4</td>
<td>183.3</td>
<td>72.6</td>
<td>181.2</td>
<td>21.3</td>
<td>113.6</td>
<td>-</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Unit in Year 2</th>
<th>1-2</th>
<th>2-2</th>
<th>3-2</th>
<th>4-2</th>
<th>5-2</th>
<th>6-2</th>
<th>7-2</th>
<th>8-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instances of assistance</td>
<td>156.8</td>
<td>200</td>
<td>56.8</td>
<td>136.5</td>
<td>135.7</td>
<td>-</td>
<td>-</td>
<td>71.1</td>
</tr>
</tbody>
</table>

In both year groups it is clear that the pattern of assistance does not follow the frequency of posting. For example in Unit 2-2, the number of assistance is twice the number of messages posted; in Unit 3-2, it is as low as only 56.8% of the messages could possibly contain a single assistance.
4. Findings

S1: by students in Year 1; S2: by students in Year 2; T1: by tutors in Year 1; T2: by Tutors in Year 2; %: percentage of assistance according to type of assistance overall.

The Table above identifies the number of occurrences of each form of assistance in Year 1 and Year 2. The Table above shows that in Year 1, more assistance was from the tutors even though the students posted more messages than the tutors (tutors provided 367 assistance in Year 1 compared to 165 from students). In Year 2, however, there is no significant difference in terms of total number of instances of assistance from the tutors (199) or students (194). Compared to the number of messages sent in this year group (75 from the tutors and 231 from the students) and since there are far fewer tutors than students, it seems that assistance is more still likely to be provided by an individual tutor than a student.

In Year 1, Scaffolding at 37% is the type of assistance most commonly found in the units’ discussion compared to the other types of assistance. Cognitive Structuring is the type of assistance that is least commonly found (0.4%). Feedback (14.3%), Instructing (27.6%) and Questioning (17.1%) are quite common type of assistance found between the two end points, suggesting that these types of assistance have significant roles in such interactions.

In terms of which type of assistance is most prevalent in the tutor or students’ postings, it shows that in Year 1, most of the instances of Scaffolding (as the most popular type of assistance) were from the students. This is followed by Instructing, although most of these were from the tutors. Questioning and Feedback were less used and mostly by the tutors. The least common form of assistance given by the students were Instructing, Modelling, Contingency Management and Cognitive Structuring. From the Table, it can be seen that assistance was more frequently given by the tutors than the students for all types of assistance except for Scaffolding, where 112 (56.9%) out of 197 incidents of assistance were given by the students.

The finding also indicates that the number of assistance occurrences is not related to the number of messages posted, but to the participants’ role. Students were more likely to provide a simple form of assistance, such as Scaffolding. Even though the tutors sent the
least number of messages overall, they remain the main source of support. They used most of the opportunities in their posting to give assistance while students did otherwise. In Year 2, the total number of assistance from both tutors and students are almost equivalent, which illustrates an increase of students’ role in giving assistance, in contrast to Year 1. Compared to Year 1, Year 2 shows a higher percentage in type of assistance used that were the least used in Year 1. These types of assistance are Cognitive Structuring, Modelling and Contingency Management.

In Year 2, the most common form of assistance given was still Scaffolding (51.1%) and mostly (two-thirds) from the students. This is followed by Questioning (19.1%), Feedback (12.5%) and Instructing (9.4%). The least common forms of assistance given by the students were still Cognitive Structuring (3.6%), Modelling (2.3%) and Contingency Management (2.0%). From the Table, it can be seen that while the students posted more messages, the total number of assistance given by the tutors and students was fairly equal (199 and 194 respectively). This instance shows the consistent contribution of tutors’ assistance throughout the courses/units. Assistance was given more frequently by the tutors for all types of assistance except for Scaffolding and Modelling. From these results, tutors have shown a larger contribution in their role of giving Feedback and Instructing compared to students. These analyses of assistance suggest that assistance is more likely to be found in tutors’ postings compared to the students’. The balance of most type of assistance to be given by either role (tutor and student) in both year groups shows a similar pattern i.e. students are most likely to provide assistance through Scaffolding and tutors through Feedback and Instructing.

5. Conclusion

To sum up, this paper discusses the methodological choices related to problems occurring in researching online learning task. Some main considerations for this study are as follows: (1) Some of the messages may not appear to display any sign of participants’ interaction of learning, for example ‘isolated’ postings. However, in trying to find the evidence of assistances and to put them into a particular perspective, these messages are included in the total numbers of messages as they have, to some extent, ‘contributed’ to the learning as a whole. As the messages might have been read by someone or someone could have learnt something from reading them, interactions are no longer important here but the evidence of assistances. (2) Even though the findings show conventional role of the tutors in providing assistances, assisted performance still can become a useful tool in judging a meaningful posting for learning activities in online environment. Teaching behaviour could be occurring in peer learning interactions that were evidenced in online learning tasks in this study. As teaching in peer learning situation is conceptualised as assisted performance, the methodology proposed in this study, is to look at the ‘proportions’ of assistance (i.e. counting the frequencies of assistance relative to the number of messages) to commensurately understand the learning evidence in such an environment.
